(54) Title: PLANTS HAVING MUTANT SEQUENCES THAT CONFER ALTERED FATTY ACID PROFILES

(57) Abstract

Seeds, plants and oils are provided having low FDA saturates; high oleic acid; low linoleic acid; high or low palmitic acid; low stearic acid; and low linoleic acid plus linolenic acid; and advantageous functional or nutritional properties. Plants are disclosed that contain a mutation in a delta-12 or delta-15 fatty acid desaturase gene. Preferred plants are rapeseed and sunflower plants. Plants carrying such mutant genes have altered fatty acid composition in seeds. In one embodiment, a plant contains a mutation in a region having the conserved motif His-Xaa-Xaa-His, found in delta-12 and delta-15 fatty acid desaturases. A preferred motif has the sequence His-Glu-Cys-Gly-His. A preferred mutation in this motif has the amino acid sequence His-Lys-Cys-Gly-His. Nucleic acid fragments are disclosed that comprise a mutant delta-12 or delta-15 fatty acid desaturase gene sequence.

PLANTS HAVING MUTANT SEQUENCES THAT CONFER ALTERED FATTY ACID PROFILES

5

Technical Field

This invention relates to Brassica seeds and plants having mutant sequences which confer altered fatty acid profiles on the seed oil. More particularly, the invention relates to mutant delta-12 and delta-15 fatty acid desaturase sequences in such plants which confer such profiles.

Background of the Invention

Diets high in saturated fats increase low density
lipoproteins (LDL) which mediate the deposition of
cholesterol on blood vessels. High plasma levels of
serum cholesterol are closely correlated with
atherosclerosis and coronary heart disease (Conner et
al., Coronary Heart Disease: Prevention, Complications,
and Treatment, pp. 43-64, 1985). By producing oilseed
Brassica varieties with reduced levels of individual and
total saturated fats in the seed oil, oil-based food
products which contain less saturated fats can be
produced. Such products will benefit public health by
reducing the incidence of atherosclerosis and coronary
heart disease.

The dietary effects of monounsaturated fats have also been shown to have dramatic effects on health. Oleic acid, the only monounsaturated fat in most edible vegetable oils, lowers LDL as effectively as linoleic acid, but does not affect high density lipoproteins (HDL) levels (Mattson, F.H., J. Am. Diet. Assoc., 89:387-391, 1989; Mensink et al., New England J. Med., 321:436-441, 1989). Oleic acid is at least as effective in lowering plasma cholesterol as a diet low in fat and high in

carbohydrates (Grundy, S.M., New England J. Med., 314:745-748, 1986; Mensink et al., New England J. Med., 321:436-441, 1989). In fact, a high oleic acid diet is preferable to low fat, high carbohydrate diets for diabetics (Garg et al., New England J. Med., 319:829-834, 1988). Diets high in monounsaturated fats are also correlated with reduced systolic blood pressure (Williams et al., J. Am. Med. Assoc., 257:3251-3256, 1987). Epidemiological studies have demonstrated that the "Mediterranean" diet, which is high in fat and monounsaturates, is not associated with coronary heart disease (Keys, A., Circulation, 44(Suppl):1, 1970).

Many breeding studies have been conducted to improve the fatty acid profile of Brassica varieties. 15 Pleines and Freidt, Fat Sci. Technol., 90(5), 167-171 (1988) describe plant lines with reduced $C_{18:3}$ levels (2.5-5.8%) combined with high oleic content (73-79%). Rakow and McGregor, J. Amer. Oil Chem. Soc., 50, 400-403 (Oct. 1973) discuss problems associated with selecting mutants 20 for linoleic and linolenic acids. In. Can. J. Plant Sci., 68, 509-511 (Apr. 1988) Stellar summer rape producing seed oil with 3% linolenic acid and 28% linoleic acid is disclosed. Roy and Tarr, Z. Pflanzenzuchtg, 95(3), 201-209 (1985) teaches transfer of 25 genes through an interspecific cross from Brassica juncea into Brassica napus resulting in a reconstituted line combining high linoleic with low linolenic acid content. Roy and Tarr, Plant Breeding, 98, 89-96 (1987) discuss prospects for development of B. napus L. having improved 30 linolenic and linolenic acid content. European Patent application 323,751 published July 12, 1989 discloses seeds and oils having greater than 79% oleic acid combined with less than 3.5% linolenic acid. Canvin, Can. J. Botany, 43, 63-69 (1965) discusses the effect of

- 3 -

temperature on the fatty acid composition of oils from several seed crops including rapeseed.

Mutations typically are induced with extremely high doses of radiation and/or chemical mutagens (Gaul, 5 H. Radiation Botany (1964) 4:155-232). High dose levels which exceed LD50, and typically reach LD90, led to maximum achievable mutation rates. In mutation breeding of Brassica varieties high levels of chemical mutagens alone or combined with radiation have induced a limited 10 number of fatty acid mutations (Rakow, G.Z. Pflanzenzuchtg (1973) 69:62-82). The low α -linolenic acid mutation derived from the Rakow mutation breeding program did not have direct commercial application because of low seed yield. The first commercial cultivar 15 using the low α -linolenic acid mutation derived in 1973 was released in 1988 as the variety Stellar (Scarth, R. et al., Can. J. Plant Sci. (1988) 68:509-511). Stellar was 20% lower yielding than commercial cultivars at the time of its release.

Canola-quality oilseed Brassica varieties with reduced levels of saturated fatty acids in the seed oil could be used to produce food products which promote cardiovascular health. Canola lines which are individually low in palmitic and stearic acid content or low in combination will reduce the levels of saturated fatty acids. Similarly, Brassica varieties with increased monounsaturate levels in the seed oil, and products derived from such oil, would improve lipid nutrition. Canola lines which are low in linoleic acid tend to have high oleic acid content, and can be used in the development of varieties having even higher oleic acid content.

Increased palmitic acid content provides a functional improvement in food applications. Oils high in palmitic acid content are particularly useful in the

- 4 -

formulation of margarines. Thus, there is a need for manufacturing purposes for oils high in palmitic acid content.

Decreased α-linolenic acid content provides a
5 functional improvement in food applications. Oils which
are low in linolenic acid have increased stability. The
rate of oxidation of lipid fatty acids increases with
higher levels of linolenic acid leading to off-flavors
and off-odors in foods. There is a need in the food
10 industry for oils low in alpha linolenic acid.

Delta-12 fatty acid desaturase (also known as oleic desaturase) is involved in the enzymatic conversion of oleic acid to linoleic acid. Delta-15 fatty acid desaturase (also known as linoleic acid desaturase) is 15 involved in the enzymatic conversion of linoleic acid to α -linolenic acid. A microsomal delta-12 desaturase has been cloned and characterized using T-DNA tagging. Okuley, et al., Plant Cell 6:147-158 (1994). nucleotide sequences of higher plant genes encoding 20 microsomal delta-12 fatty acid desaturase are described in Lightner et al., WO94/11516. Sequences of higher plant genes encoding microsomal and plastid delta-15 fatty acid desaturases are disclosed in Yadav, N., et al., Plant Physiol., 103:467-476 (1993), WO 93/11245 and 25 Arondel, V. et al., Science, 258:1353-1355 (1992). However, there are no teachings that disclose mutations in delta-12 or delta-15 fatty acid desaturase coding sequences from plants. Furthermore, no methods have been described for developing plant lines that contain delta-30 12 or delta-15 fatty acid desaturase gene sequence mutations effective for altering the fatty acid composition of seeds.

- 5 -

Summary of the Invention

The present invention comprises canola seeds, plant lines producing seeds, and plants producing seed, said seeds having a maximum content of FDA saturates of about 5% and a maximum erucic acid content of about 2% based upon total extractable oil and belonging to a line in which said saturates content has been stabilized for both the generation to which the seed belongs and its parent generation. Progeny of said seeds and canola oil having a maximum erucic acid content of about 2%, based upon total extractable oil, are additional aspects of this invention. Preferred are seeds, plant lines producing seeds, and plants producing seeds, said seeds having an FDA saturates content of from about 4.2% to about 5.0% based upon total extractable oil.

The present invention further comprises Brassica seeds, plant lines producing seeds, and plants producing seeds, said seeds having a minimum oleic acid content of about 71% based upon total extractable oil and belonging 20 to a line in which said oleic acid content has been stabilized for both the generation to which the seed belongs and its parent generation. A further aspect of this invention is such high oleic acid seeds additionally having a maximum erucic acid content of about 2% based 25 upon total extractable oil. Progeny of said seeds; and Brassica oil having 1) a minimum oleic acid content of about 71% or 2) a minimum oleic acid content of about 71% and a maximum erucic content of about 2% are also included in this invention. Preferred are seeds, plant 30 lines producing seeds, and plants producing seeds, said seeds having an oleic acid content of from about 71.2% to about 78.3% based upon total extractable oil.

The present invention further comprises canola seeds, plant lines producing seeds, and plants producing seeds, said seeds having a maximum linoleic acid content

of about 14% and a maximum erucic acid content of about 2% based upon total extractable oil and belonging to a line in which said acid content is stabilized for both the generation to which the seed belongs and its parent generation. Progeny of said seeds and canola oil having a maximum linoleic acid content of about 14% and a maximum erucic acid content of about 2%, are additional aspects of this invention. Preferred are seeds, plant lines producing seeds, and plants producing seeds, said seeds having a linoleic acid content of from about 8.4% to about 9.4% based upon total extractable oil.

seeds, plant lines producing seeds, and plants producing seeds, said seeds having a maximum palmitic acid content of about 3.5% and a maximum erucic acid content of about 2% based on total extractable oil and belonging to a line in which said acid content is stabilized for both the generation to which the seed belongs and its parent generation. Progeny of said seeds and canola having a maximum palmitic acid content of about 3.5% and a maximum erucic acid content of about 2%, are additional aspects of this invention. Preferred are seeds, plant lines producing seeds, and plants producing seeds, said seeds having a palmitic acid content of from about 2.7% to about 3.1% based upon total extractable oil.

seeds, plant lines producing seeds, and plants producing seeds, said seeds having a minimum palmitic acid content of about 9.0% based upon total extractable oil and belonging to a line in which said acid content is stabilized for both the generation to which the seed belongs and its parent generation. A further aspect of this invention is such high palmitic acid seeds additionally having a maximum erucic acid content of about 2% based upon total extractable oil. Progeny of

- 7 -

said seeds; and Brassica oil having 1) a minimum palmitic acid content of about 9.0%, or 2) a minimum palmitic acid content of about 9.0% and a maximum erucic acid content of about 2% are also included in this invention.

5 Preferred are seeds, plant lines producing seeds, and plants producing seeds, said seeds having a palmitic acid content of from about 9.1% to about 11.7% based upon total extractable oil.

The present invention further comprises Brassica

10 seeds, plant lines producing seeds, and plants producing seeds, said seeds having a maximum stearic acid content of about 1.1% based upon total extractable oil and belonging to a line in which said acid content is stabilized for both the generation to which the seed

15 belongs and its parent generation. Progeny of said seeds have a canola oil having a maximum stearic acid content of about 1.1% and maximum erucic acid content of about 2%. Preferred are seeds, plant lines producing seeds, and plants producing seeds having a palmitic acid content of from about 0.8% to about 1.1% based on total extractable oil.

seeds, plant lines producing seeds, and plants producing seeds, said seeds having a sum of linoleic acid content and linolenic acid content of a maximum of about 14% based upon total extractable oil and belonging to a line in which said acid content is stabilized for both the generation to which the seed belongs and its parent generation. Progeny of said seeds have a canola oil having a sum of linoleic acid content and linolenic acid content of a maximum of about 14% and a maximum erucic acid content of about 2%. Preferred are seeds, plant lines producing seeds, and plants producing seeds having a sum of linoleic acid content and linolenic acid content

- 8 -

of from about 11.8% to about 12.5% based on total extractable oil.

The invention further comprises Brassicaceae or Helianthus seeds, plants and plant lines having at least 5 one mutation that controls the levels of unsaturated fatty acids in plants. One embodiment of the invention is an isolated nucleic acid fragment comprising a nucleotide sequence encoding a mutant delta-12 fatty acid desaturase conferring altered fatty composition in seeds 10 when the fragment is present in a plant. A preferred sequence comprises a mutant sequence as shown in SEQ ID NO:3. Another embodiment of the invention is an isolated nucleic acid fragment comprising a nucleotide sequence encoding a mutant delta-15 fatty acid desaturase. A 15 plant in this embodiment may be soybean, oilseed Brassica species, sunflower, castor bean or corn. The mutant sequence may be derived from, for example, a Brassica napus, Brassica rapa, Brassica juncea or Helianthus delta-12 or delta-15 gene.

Another embodiment of the invention involves a method of producing a Brassicaceae or Helianthus plant line comprising the steps of: (a) inducing mutagenesis in cells of a starting variety of a Brassicaceae or Helianthus species; (b) obtaining progeny plants from the mutagenized cells; (c) identifying progeny plants that contain a mutation in a delta-12 or delta-15 fatty acid desaturase gene; and (d) producing a plant line by selfing.

Yet another embodiment of the invention involves a method of producing plant lines containing altered levels of unsaturated fatty acids comprising: (a) crossing a first plant with a second plant having a mutant delta-12 or delta-15 fatty acid desaturase; (b) obtaining seeds from the cross of step (a); (c) growing fertile plants of from such seeds; (d) obtaining progeny seed the plants of

- 9 -

step (c); and (e) identifying those seeds among the progeny that have altered fatty acid composition. Suitable plants are soybean, rapeseed, sunflower, safflower, castor bean and corn. Preferred plants are rapeseed and sunflower.

The invention is also embodied in vegetable oil obtained from plants disclosed herein, which vegetable oil has an altered fatty acid composition.

Brief Description of the Figures

10 Figure 1 is a histogram showing the frequency distribution of seed oil oleic acid $(C_{18:1})$ content in a segregating population of a Q508 X Westar cross. The bar labeled WSGA 1A represents the $C_{18:1}$ content of the Westar parent. The bar labeled Q508 represents the $C_{18:1}$ content of the Q508 parent.

Description of the Preferred Embodiments

The U.S. Food and Drug Administration defines saturated fatty acids as the sum of lauric $(C_{12:0})$, myristic $(C_{14:0})$, palmitic $(C_{16:0})$ and stearic $(C_{18:0})$ acids. The term "FDA saturates" as used herein means this abovedefined sum. Unless total saturate content is specified, the saturated fatty acid values expressed here include only "FDA saturates."

All percent fatty acids herein are percent by 25 weight of the oil of which the fatty acid is a component.

As used herein, a "line" is a group of plants that display little or no genetic variation between individuals for at least one trait. Such lines may be created by several generations of self-pollination and selection, or vegetative propagation from a single parent using tissue or cell culture techniques. As used herein, the term "variety" refers to a line which is used for commercial production.

30

- 10 -

The term "mutagenesis" refers to the use of a mutagenic agent to induce random genetic mutations within a population of individuals. The treated population, or a subsequent generation of that population, is then 5 screened for usable trait(s) that result from the mutations. A "population" is any group of individuals that share a common gene pool. As used herein " M_0 " is untreated seed. As used herein, "M," is the seed (and resulting plants) exposed to a mutagenic agent, while "M2" 10 is the progeny (seeds and plants) of self-pollinated M, plants, "M3" is the progeny of self-pollinated M2 plants, and "M4" is the progeny of self-pollinated M3 plants. " M_5 " is the progeny of self-pollinated M_4 plants. " M_6 ", "M₇", etc. are each the progeny of self-pollinated plants 15 of the previous generation. The term "selfed" as used herein means self-pollinated.

"Stability" or "stable" as used herein means that with respect to a given fatty acid component, the component is maintained from generation to generation for at least two generations and preferably at least three generations at substantially the same level, e.g., preferably ±5%. The method of invention is capable of creating lines with improved fatty acid compositions stable up to ±5% from generation to generation. The above stability may be affected by temperature, location, stress and time of planting. Thus, comparison of fatty acid profiles should be made from seeds produced under similar growing conditions. Stability may be measured based on knowledge of prior generation.

Intensive breeding has produced Brassica plants whose seed oil contains less than 2% erucic acid. The same varieties have also been bred so that the defatted meal contains less than 30 μ mol glucosinolates/gram. "Canola" as used herein refers to plant variety seed or

PCT/US96/20090 WO 97/21340

- 11 -

oil which contains less than 2% erucic acid $(C_{22:1})$, and meal with less than 30 μ mol glucosinolates/gram.

Applicants have discovered plants with mutations in a delta-12 fatty acid desaturase gene. Such plants 5 have useful alterations in the fatty acid compositions of the seed oil. Such mutations confer, for example, an elevated oleic acid content, a decreased, stabilized linoleic acid content, or both elevated oleic acid and decreased, stabilized linoleic acid content.

Applicants have further discovered plants with mutations in a delta-15 fatty acid desaturase gene. plants have useful alterations in the fatty acid composition of the seed oil, e.g., a decreased, stabilized level of α -linolenic acid.

10

15

25

Applicants have further discovered isolated nucleic acid fragments comprising sequences that carry mutations within the coding sequence of delta-12 or delta-15 desaturases. The mutations confer desirable alterations in fatty acid levels in the seed oil of 20 plants carrying such mutations. Delta-12 fatty acid desaturase is also known as omega-6 fatty acid desaturase and is sometimes referred to herein as 12-DES. Delta-15 fatty acid desaturase is also known on omega-3 fatty acid desaturase and is sometimes referred to herein as 15-DES.

A nucleic acid fragment of the invention contains a mutation in a microsomal delta-12 fatty acid desaturase coding sequence or in a microsomal delta-15 fatty acid desaturase coding sequence. Such a mutation renders the resulting desaturase gene product non-functional in 30 plants, relative to the function of the gene product encoded by the wild-type sequence. The non-functionality of the 12-DES gene product can be inferred from the decreased level of reaction product (linoleic acid) and increased level of substrate (oleic acid) in plant 35 tissues expressing the mutant sequence, compared to the

corresponding levels in plant tissues expressing the wild-type sequence. The non-functionality of the 15-DES gene product can be inferred from the decreased level of reaction product (α-linolenic acid) and the increased level of substrate (linoleic acid) in plant tissues expressing the mutant sequence, compared to the corresponding levels in plant tissues expressing the wild-type sequence.

A nucleic acid fragment of the invention may

comprise a portion of the coding sequence, e.g., at least about 10 nucleotides, provided that the fragment contains at least one mutation in the coding sequence. The length of a desired fragment depends upon the purpose for which the fragment will be used, e.g., PCR primer, sitedirected mutagenesis and the like. In one embodiment, a nucleic acid fragment of the invention comprises the full length coding sequence of a mutant delta-12 or mutant delta-15 fatty acid desaturase.

A mutation in a nucleic acid fragment of the
invention may be in any portion of the coding sequence
that renders the resulting gene product non-functional.
Suitable types of mutations include, without limitation,
insertions of nucleotides, deletions of nucleotides, or
transitions and transversions in the wild-type coding
sequence. Such mutations result in insertions of one or
more amino acids, deletions of one or more amino acids,
and non-conservative amino acid substitutions in the
corresponding gene product. In some embodiments, the
sequence of a nucleic acid fragment may comprise more
than one mutation or more than one type of mutation.

Insertion or deletion of amino acids in a coding sequence may, for example, disrupt the conformation of essential alpha-helical or beta-pleated sheet regions of the resulting gene product. Amino acid insertions or deletions may also disrupt binding or catalytic sites

WO 97/21340

- 13 -

PCT/US96/20090

important for gene product activity. It is known in the art that the insertion or deletion of a larger number of contiguous amino acids is more likely to render the gene product non-functional, compared to a smaller number of inserted or deleted amino acids.

Non-conservative amino acid substitutions may replace an amino acid of one class with an amino acid of a different class. Non-conservative substitutions may make a substantial change in the charge or hydrophobicity of the gene product. Non-conservative amino acid substitutions may also make a substantial change in the bulk of the residue side chain, e.g., substituting an alanyl residue for a isoleucyl residue.

Examples of non-conservative substitutions include

the substitution of a basic amino acid for a non-polar
amino acid, or a polar amino acid for an acidic amino
acid. Because there are only 20 amino acids encoded in a
gene, substitutions that result in a non-functional gene
product may be determined by routine experimentation,

incorporating amino acids of a different class in the
region of the gene product targeted for mutation.

Preferred mutations are in a region of the nucleic acid having an amino acid sequence motif that is conserved among delta-12 fatty acid desaturases or delta-15 fatty acid desaturases, such as a His-Xaa-Xaa-Xaa-His motif (Tables 1-3). An example of a suitable region has a conserved HECGH motif that is found, for example, in nucleotides corresponding to amino acids 105 to 109 of the Arabidopsis and Brassica delta-12 desaturase

30 sequences, in nucleotides corresponding to amino acids 101 to 105 of the soybean delta-12 desaturase sequence and in nucleotides corresponding to amino acids 111 to 115 of the maize delta-12 desaturase sequence. See e.g., WO 94/115116; Okuley et al., Plant Cell 6:147-158 (1994).

described in Alberts, B. et al., Molecular Biology of the Cell, 3rd edition, Garland Publishing, New York, 1994.

Amino acids flanking this motif are also highly conserved among delta-12 and delta-15 desaturases and are also suitable candidates for mutations in fragments of the invention. An illustrative embodiment of a mutation in a nucleic acid fragment of the invention is a Glu to Lys substitution in the HECGH motif of a Brassica microsomal delta-12 desaturase sequence, either the D form or the F form. This mutation results in the sequence HECGH being changed to HKCGH as seen by comparing SEQ ID NO:2 (wildtype D form) to SEQ ID NO:4 (mutant D form).

A similar motif may be found at amino acids 101 to 105 of the Arabidopsis microsomal delta-15 fatty acid desaturase, as well as in the corresponding rape and soybean desaturases (Table 5). See, e.g., WO 93/11245; Arondel, V. et al., Science, 258:1153-1155 (1992); Yadav, N. et al., Plant Physiol., 103:467-476 (1993). Plastid delta-15 fatty acids have a similar motif (Table 5).

Among the types of mutations in an HECGH motif
that render the resulting gene product non-functional are
non-conservative substitutions. An illustrative example
of a non-conservative substitution is substitution of a
glycine residue for either the first or second histidine.

Such a substitution replaces a polar residue (histidine)
with a non-polar residue (glycine). Another type of
mutation that renders the resulting gene product nonfunctional is an insertion mutation, e.g., insertion of a
glycine between the cystine and glutamic acid residues in
the HECGH motif.

Other regions having suitable conserved amino acid motifs include the HRRHH motif shown in Table 2, the HRTHH motif shown in Table 6 and the HVAHH motif shown in Table 3. See, e.g., WO 94/115116; Hitz, W. et al., Plant

- 15 -

Physiol., 105:635-641 (1994); Okuley, J., et al., supra; and Yadav, N. et al., supra.

Another region suitable for a mutation in a delta12 desaturase sequence contains the motif KYLNNP at
5 nucleotides corresponding to amino acids 171 to 175 of
the Brassica desaturase sequence. An illustrative
example of a mutation is this region is a Leu to His
substitution, resulting in the amino acid sequence (Table
4) KYHNN (Compare wild-type SEQ ID NO:6 to mutant SEQ ID
10 NO:8).

The conservation of amino acid motifs and their relative positions indicates that regions of a delta-12 or delta-15 fatty acid desaturase that can be mutated in 15 one species to generate a non-functional desaturase can be mutated in the corresponding region from other species to generate a non-functional 12-DES or 15-DES gene product in that species.

Mutations in any of the regions of Tables 1-6 are 20 specifically included within the scope of the invention, provided that such mutation (or mutations) renders the resulting desaturase gene product non-functional, as discussed hereinabove.

A nucleic acid fragment containing a mutant 25 sequence can be generated by techniques known to the skilled artisan. Such techniques include, without limitation, site-directed mutagenesis of wild-type sequences and direct synthesis using automated DNA synthesizers.

A nucleic acid fragment containing a mutant sequence can also be generated by mutagenesis of plant seeds or regenerable plant tissue by, e.g., ethyl methane sulfonate, X-rays or other mutagens. With mutagenesis, mutant plants having the desired fatty acid phenotype in 35 seeds are identified by known techniques and a nucleic acid fragment containing the desired mutation is isolated from genomic DNA or RNA of the mutant line. The site of

- 18 -

the specific mutation is then determined by sequencing the coding region of the 12-DES or 15-DES gene.

Alternatively, labeled nucleic acid probes that are specific for desired mutational events can be used to rapidly screen a mutagenized population.

Seeds of Westar, a Canadian (Brassica napus) spring canola variety, were subjected to chemical mutagenesis. Mutagenized seeds were planted in the greenhouse and the plants were self-pollinated. The 10 progeny plants were individually analyzed for fatty acid composition, and regrown either in the greenhouse or in the field. After four successive generations of self-pollinations, followed by chemical analysis of the seed oil at each cycle, several lines were shown to carry stably inherited mutations in specific fatty acid components, including reduced palmitic acid (C_{16:0}), increased palmitic acid, reduced stearic acid (C_{18:0}), increased oleic acid (C_{18:1}), reduced linoleic acid (C_{18:2}) and reduced linolenic acid (C_{18:3}), in the seed oil.

The general experimental scheme for developing lines with stable fatty acid mutations is shown in Scheme I hereinafter.

STABLE FATTY ACID MUTANTS

Westar seeds (M_0) were mutagenized with ethylmethanesulfonate (EMS). Westar is a registered Canadian spring variety with canola quality. The fatty 40 acid composition of field-grown Westar, 3.9% C_{16:0}, 1.9% $C_{18:0}$, 67.5% $C_{18:1}$, 17.6% $C_{18:2}$, 7.4% $C_{18:3}$, <2% $C20:1 + C_{22:1}$, has remained stable under commercial production, with $<\pm$ 10% deviation, since 1982. The disclosed method may be applied to all oilseed Brassica species, and to both 45 Spring and Winter maturing types within each species. Physical mutagens, including but not limited to X-rays,

UV rays, and other physical treatments which cause chromosome damage, and other chemical mutagens, including but not limited to ethidium bromide, nitrosoguanidine, diepoxybutane etc. may also be used to induce mutations.

The mutagenesis treatment may also be applied to other stages of plant development, including but not limited to cell cultures, embryos, microspores and shoot apices.

The M₁ seeds were planted in the greenhouse and M₁ plants were individually self-pollinated.

M₂ seed was harvested from the greenhouse and planted in the field in a plant-to-row design. Each plot contained six rows, and five M₂ lines were planted in each plot. Every other plot contained a row of non-mutagenized Westar as a control. Based on gas chromatographic analysis of M₂ seed, those lines which had altered fatty acid composition were self-pollinated and individually harvested.

M₃ seeds were evaluated for mutations on the basis of a Z-distribution. An extremely stringent 1 in 10,000 rejection rate was employed to establish statistical thresholds to distinguish mutation events from existing variation. Mean and standard deviation values were determined from the non-mutagenized Westar control population in the field. The upper and lower statistical thresholds for each fatty acid were determined from the mean value of the population ± the standard deviation, multiplied by the Z-distribution. Based on a population size of 10,000, the confidence interval is 99.99%.

Seeds (M₃) from those M₂ lines which exceeded 30 either the upper or lower statistical thresholds were replanted in the greenhouse and self-pollinated. This planting also included Westar controls. The M₄ seed was re-analyzed using new statistical thresholds established with a new control population. Those M₄ lines which 35 exceeded the new statistical thresholds for selected

- 21 -

fatty acid compositions were advanced to the nursery. Following self-pollination, M₅ seed from the field were re-analyzed once again for fatty acid composition. Those lines which remained stable for the selected fatty acids were considered stable mutations.

"Stable mutations" as used herein are defined as M_s or more advanced lines which maintain a selected altered fatty acid profile for a minimum of three generations, including a minimum of two generations under field conditions, and exceeding established statistical thresholds for a minimum of two generations, as determined by gas chromatographic analysis of a minimum of 10 randomly selected seeds bulked together. Alternatively, stability may be measured in the same way by comparing to subsequent generations. In subsequent generations, stability is defined as having similar fatty acid profiles in the seed as that of the prior or subsequent generation when grown under substantially similar conditions.

The amount of variability for fatty acid content in a seed population is quite significant when single seeds are analyzed. Randomly selected single seeds and a ten seed bulk sample of a commercial variety were compared. Significant variation among the single seeds was detected (Table A). The half-seed technique (Downey, R.K. and B.L. Harvey, Can. J. Plant Sci., 43:271 [1963]) in which one cotyledon of the germinating seed is analyzed for fatty acid composition and the remaining embryo grown into a plant has been very useful to plant breeding work to select individuals in a population for further generation analysis. The large variation seen in the single seed analysis (Table A) is reflected in the half-seed technique.

Plant breeders using the half-seed technique have found it unreliable in selecting stable genetically controlled fatty acid mutations (Stefanson, B.R., In; High and Low Erucic Acid Rapeseed Oils, Ed. N.T. Kenthies, Academic Press, Inc., Canada (1983) pp. 145-159). Although valuable in selecting individuals from a population, the selected traits are not always transmitted to subsequent generations (Rakow, G. and McGregor, D.I., J. Amer. Oil Chem. Soc. (1973) 50:400-403. To determine the genetic stability of the selected plants several self-pollinated generations are required (Robelen, G. In: Biotechnology for the Oils and Fats Industry, Ed. C. Ratledge, P. Dawson and J. Rattray,

- 23 -

American Oil Chemists Society (1984) pp. 97-105) with chemical analysis of a bulk seed sample.

Mutation breeding has traditionally produced plants carrying, in addition to the trait of interest,

5 multiple, deleterious traits, e.g., reduced plant vigor and reduced fertility. Such traits may indirectly affect fatty acid composition, producing an unstable mutation; and/or reduce yield, thereby reducing the commercial utility of the invention. To eliminate the occurrence of deleterious mutations and reduce the load of mutations carried by the plant a low mutagen dose was used in the seed treatments to create an LD30 population. This allowed for the rapid selection of single gene mutations for fatty acid traits in agronomic backgrounds which produce acceptable yields.

Other than changes in the fatty acid composition of the seed oil, the mutant lines described here have normal plant phenotype when grown under field conditions, and are commercially useful. "Commercial utility" is defined as having a yield, as measured by total pounds of seed or oil produced per acre, within 15% of the average yield of the starting (Mo) canola variety grown in the same region. To be commercially useful, plant vigor and high fertility are such that the crop can be produced in this yield by farmers using conventional farming equipment, and the oil with altered fatty acid composition can be extracted using conventional crushing and extraction equipment.

The seeds of several different fatty acid lines name to been deposited with the American Type Culture Collection and have the following accession numbers.

- 24 -

	<u>Line</u>	Accession No.	Deposit Date

In some plant species or varieties more than one form of endogenous microsomal delta-12 desaturase may be found. In amphidiploids, each form may be derived from one of the parent genomes making up the species under consideration. Plants with mutations in both forms have a fatty acid profile that differs from plants with a mutation in only one form. An example of such a plant is 20 Brassica napus line Q508, a doubly-mutagenized line containing a mutant D-form of delta-12 desaturase (SEQ ID NO:1) and a mutant F-form of delta-12 desaturase (SEQ ID NO:5).

Preferred host or recipient organisms for

introduction of a nucleic acid fragment of the invention are the oil-producing species, such as soybean (Glycine max), rapeseed (e.g., Brassica napus, B. rapa and B. juncea), sunflower (Helianthus annus), castor bean (Ricinus communis), corn (Zea mays), and safflower

(Carthamus tinctorius).

Plants according to the invention preferably contain an altered fatty acid profile. For example, oil obtained from seeds of such plants may have from about 69 to about 90% oleic acid, based on the total fatty acid composition of the seed. Such oil preferably has from about 74 to about 90% oleic acid, more preferably from about 80 to about 90% oleic acid. In some embodiments, oil obtained from seeds produced by plants of the

- 25 -

invention may have from about 2.0% to about 5.0% saturated fatty acids, based on total fatty acid composition of the seeds. In some embodiments, oil obtained from seeds of the invention may have from about 1.0% to about 14.0% linoleic acid, or from about 0.5% to about 10.0% α-linolenic acid.

In one embodiment of the claimed invention, a plant contains both a 12-DES mutation and a 15-DES mutation. Such plants can have a fatty acid composition comprising very high oleic acid and very low alphalinolenic acid levels. Mutations in 12-DES and 15-DES may be combined in a plant by making a genetic cross between 12-DES and 15-DES single mutant lines. A plant having a mutation in delta-12 fatty acid desaturase is crossed or mated with a second plant having a mutation in delta-15 fatty acid desaturase. Seeds produced from the cross are planted and the resulting plants are selfed in order to obtain progeny seeds. These progeny seeds are then screened in order to identify those seeds carrying both mutant genes.

Alternatively, a line possessing either a 12-DES or a 15-DES mutation can be subjected to mutagenesis to generate a plant or plant line having mutations in both 12-DES and 15-DES. For example, the IMC 129 line has a 25 mutation in the coding region (Glu₁₀₆ to Lys₁₀₆) of the D form of the microsomal delta-12 desaturase structural gene. Cells (e.g., seeds) of this line can be mutagenized to induce a mutation in a 15-DES gene, resulting in a plant or plant line carrying a mutation in a delta-12 fatty acid desaturase gene and a mutation in a delta-15 fatty acid desaturase gene.

Progeny includes descendants of a particular plant or plant line, e.g., seeds developed on an instant plant. Progeny of an instant plant include seeds formed on F_1

30 DES or 15-DES.

- 26 -

 F_2 , F_3 , and subsequent generation plants, or seeds formed on BC_1 , BC_2 , BC_3 and subsequent generation plants.

Those seeds having an altered fatty acid composition may be identified by techniques known to the skilled artisan, e.g., gas-liquid chromatography (GLC) analysis of a bulked seed sample or of a single halfseed. Half-seed analysis is well known in the art to be useful because the viability of the embryo is maintained and thus those seeds having a desired fatty acid profile may be planted to from the next generation. However, half-seed analysis is also known to be an inaccurate representation of genotype of the seed being analyzed. Bulk seed analysis typically yields a more accurate representation of the fatty acid profile of a given genotype.

The nucleic acid fragments of the invention can be used as markers in plant genetic mapping and plant breeding programs. Such markers may include restriction fragment length polymorphism (RFLP), random amplification polymorphism detection (RAPD), polymerase chain reaction (PCR) or self-sustained sequence replication (3SR) markers, for example. Marker-assisted breeding techniques may be used to identify and follow a desired fatty acid composition during the breeding process.

25 Marker-assisted breeding techniques may be used in addition to, or as an alternative to, other sorts of identification techniques. An example of marker-assisted breeding is the use of PCR primers that specifically amplify a sequence containing a desired mutation in 12-

Methods according to the invention are useful in that the resulting plants and plant lines have desirable seed fatty acid compositions as well as superior agronomic properties compared to known lines having 35 altered seed fatty acid composition. Superior agronomic

- 27 -

characteristics include, for example, increased seed germination percentage, increased seedling vigor, increased resistance to seedling fungal diseases (damping off, root rot and the like), increased yield, and improved standability.

While the invention is susceptible to various modifications and alternative forms, certain specific embodiments thereof are described in the general methods and examples set forth below. For example the invention 10 may be applied to all Brassica species, including B. rapa, B. juncea, and B. hirta, to produce substantially similar results. It should be understood, however, that these examples are not intended to limit the invention to the particular forms disclosed but, instead the invention 15 is to cover all modifications, equivalents and alternatives falling within the scope of the invention. This includes the use of somaclonal variation; physical or chemical mutagenesis of plant parts; anther, microspore or ovary culture followed by chromosome 20 doubling; or self- or cross-pollination to transmit the fatty acid trait, alone or in combination with other traits, to develop new Brassica lines.

EXAMPLE 1

Selection of Low FDA Saturates

Prior to mutagenesis, 30,000 seeds of B. napus cv.
Westar seeds were preimbibed in 300-seed lots for two
hours on wet filter paper to soften the seed coat. The
preimbibed seeds were placed in 80 mM
ethylmethanesulfonate (EMS) for four hours. Following
mutagenesis, the seeds were rinsed three times in
distilled water. The seeds were sown in 48-well flats
containing Pro-Mix. Sixty-eight percent of the
mutagenized seed germinated. The plants were maintained
at 25°C/15°C, 14/10 hr day/night conditions in the

greenhouse. At flowering, each plant was individually self-pollinated.

M₂ seed from individual plants were individually catalogued and stored, approximately 15,000 M₂ lines was 5 planted in a summer nursery in Carman, Manitoba. The seed from each selfed plant were planted in 3-meter rows with 6-inch row spacing. Westar was planted as the check variety. Selected lines in the field were selfed by bagging the main raceme of each plant. At maturity, the selfed plants were individually harvested and seeds were catalogued and stored to ensure that the source of the seed was known.

Self-pollinated M₃ seed and Westar controls were analyzed in 10-seed bulk samples for fatty acid

composition via gas chromatography. Statistical thresholds for each fatty acid component were established using a Z-distribution with a stringency level of 1 in 10,000. The selected M₃ seeds were planted in the greenhouse along with Westar controls. The seed was sown in 4-inch pots containing Pro-Mix soil and the plants were maintained at 25°C/15°C, 14/10 hr day/night cycle in the greenhouse. At flowering, the terminal raceme was self-pollinated by bagging. At maturity, selfed M₄ seed was individually harvested from each plant, labelled, and stored to ensure that the source of the seed was known.

The M₄ seed was analyzed in 10-seed bulk samples. Statistical thresholds for each fatty acid component were established from 259 control samples using a Z-distribution of 1 in 800. Selected M₄ lines were planted in a field trial in Carman, Manitoba in 3-meter rows with 6-inch spacing. Ten M₄ plants in each row were bagged for self-pollination. At maturity, the selfed plants were individually harvested and the open pollinated plants in the row were bulk harvested. The M₅ seed from single

- 29 -

plant selections was analyzed in 10-seed bulk samples and the bulk row harvest in 50-seed bulk samples.

Selected M_5 lines were planted in the greenhouse along with Westar controls. The seed was grown as previously described. At flowering the terminal raceme was self-pollinated by bagging. At maturity, selfed M_6 seed was individually harvested from each plant and analyzed in 10-seed bulk samples for fatty acid composition.

10 Selected M₆ lines were entered into field trials in Eastern Idaho. The four trial locations were selected for the wide variability in growing conditions. The locations included Burley, Tetonia, Lamont and Shelley (Table I). The lines were planted in four 3-meter rows with an 8-inch spacing, each plot was replicated four times. The planting design was determined using a Randomized Complete Block Designed. The commercial cultivar Westar was used as a check cultivar. At maturity the plots were harvested to determine yield. Yield of the entries in the trial was determined by taking the statistical average of the four replications. The Least Significant Difference Test was used to rank the entries in the randomized complete block design.

TABLE I

25	Trial Loc	ations for Selected Fatty Acid Mutants
	LOCATION	SITE CHARACTERIZATIONS
	BURLEY	Irrigated. Long season. High temperatures during flowering.
	TETONIA	Dryland. Short season. Cool temperatures.
30	LAMONT	Dryland. Short season. Cool temperatures.
	SHELLEY	Irrigated. Medium season. High temperatures during flowering.

To determine the fatty acid profile of entries, plants in each plot were bagged for self-pollination. The M_7 seed from single plants was analyzed for fatty acids in ten-seed bulk samples.

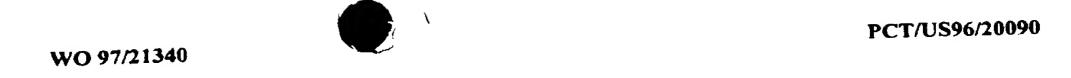

5 To determine the genetic relationships of the selected fatty acid mutants crosses were made. Flowers of M₆ or later generation mutations were used in crossing. F₁ seed was harvested and analyzed for fatty acid composition to determine the mode of gene action. The F₁ 10 progeny were planted in the greenhouse. The resulting plants were self-pollinated, the F₂ seed harvested and analyzed for fatty acid composition for allelism studies. The F₂ seed and parent line seed was planted in the greenhouse, individual plants were self-pollinated. The F₃ seed of individual plants was tested for fatty acid composition using 10-seed bulk samples as described previously.

In the analysis of some genetic relationships dihaploid populations were made from the microspores of the F₁ hybrids. Self-pollinated seed from dihaploid plants were analyzed for fatty acid analysis using methods described previously.

For chemical analysis, 10-seed bulk samples were hand ground with a glass rod in a 15-mL polypropylene

25 tube and extracted in 1.2 mL 0.25 N KOH in 1:1

ether/methanol. The sample was vortexed for 30 sec. and heated for 60 sec. in a 60°C water bath. Four mL of saturated NaCl and 2.4 mL of iso-octane were added, and the mixture was vortexed again. After phase separation, 600 μL of the upper organic phase were pipetted into individual vials and stored under nitrogen at -5°C. One μL samples were injected into a Supelco SP-2330 fused silica capillary column (0.25 mm ID, 30 M length, 0.20 μm df).

- 31 -

The gas chromatograph was set at 180°C for 5.5 minutes, then programmed for a 2°C/minute increase to 212°C, and held at this temperature for 1.5 minutes. Total run time was 23 minutes. Chromatography settings 5 were: Column head pressure - 15 psi, Column flow (He) -0.7 mL/min., Auxiliary and Column flow - 33 mL/min., Hydrogen flow - 33 mL/min., Air flow - 400 mL/min., Injector temperature - 250°C, Detector temperature -300°C, Split vent - 1/15.

Table II describes the upper and lower statistical 10 thresholds for each fatty acid of interest.

Sats=Total Saturate Content

At the M_3 generation, twelve lines exceeded the lower statistical threshold for palmitic acid ($\leq 3.3\%$). 30 Line W13097.4 had 3.1% palmitic acid and an FDA saturate content of 4.5%. After a cycle in the greenhouse, M_4 seed

- 32 -

from line W13097.4 (designated line A144) was analyzed. Line W13097.4.1(A144.1) had 3.1% $C_{16:0}$, exceeding the lower statistical threshold of 3.6%. The FDA saturate content for A144.1 was 4.5%. The fatty acid compositions for the M_3 , M_4 and M_5 generations of this family are summarized in Table III.

EXAMPLE 2

An additional low FDA saturate line, designated A149.3 (ATCC 40814), was also produced by the method of Example 1. A 50-seed bulk analysis of this line showed the following fatty acid composition: C_{16:0} - 3.6%, C_{18:0} - 1.4%, C_{18:1} - 65.5%, C_{18:2} - 18.3%, C_{18:3} - 8.2%, FDA Sats - 5.0%, Total Sats - 5.9%. This line has also stably maintained its mutant fatty acid composition to the M₅ generation. In a multiple location replicated trial the yield of A149 was not significantly different in yield from the parent cultivar Westar.

20 EXAMPLE 3

An additional low palmitic acid and low FDA saturate line, designated M3094.4 (ATCC 75023), was also produced by the method of Example 1. A 10-seed bulk analysis of this line showed the following fatty acid composition: $C_{16:0} - 2.7\%$, $C_{18:0} - 1.6\%$, $C_{18:1} - 66.6\%$, $C_{18:2} - 20.0\%$, $C_{18:3} - 6.1\%$, $C_{20:1} - 1.4\%$, $C_{22:1} - 0.0\%$, FDA Saturate 4.3%, Total Saturates - 5.2%. This line has stably maintained its mutant fatty acid composition to the Ms generation. In a single replicated trial the yield of M3094 was not significantly different in yield from the parent cultivar.

M3094.4 was crossed to A144, a low palmitic acid mutation (Example 1) for allelism studies. Fatty acid composition of the F_2 seed showed the two lines to be

15

- 36 -

allelic. The mutational events in A144 and M3094, although different in origin, are in the same gene.

EXAMPLE 4

In the studies of Example 1, at the M₃ generation,

470 lines exceed the upper statistical threshold for
palmitic acid (≥4.3%). One M₃ line, W14538.6, contained

9.2% palmitic acid. Selfed progenies of this line, since
designated M3007.4 (ATCC 75022), continued to exceed to
the upper statistical threshold for high palmitic acid at

10 both the M₄ and M₅ generations with palmitic acid levels
of 11.7% and 9.1%, respectively. The fatty acid
composition of this high palmitic acid mutant, which was
stable to the M₃ generation under both field and
greenhouse conditions, is summarized in Table VI.

TABLE VI

An additional M₅ line, M3051.10, contained 0.9% and 1.1% stearic acid in the greenhouse and field respectively. A ten-seed analysis of this line showed 15 the following fatty acid composition: C_{16:0} - 3.9%, C_{18:0} - 1.1%, C_{18:1} - 61.7%, C_{18:2} - 23.0%, C_{18:3} - 7.6%, FDA saturates - 5.0%, Total Saturates - 5.8%. In a single location replicated yield trial M3051.10 was not significantly different in yield from the parent cultivar 20 Westar. M3051.10 was crossed to M3052.1 for allelism studies. Fatty acid composition of the F₂ seed showed the two lines to be allelic. The mutational events in M3051.10 and M3052.1 although different in origin were in the same gene.

An additional M₅ line, M3054.7, contained 1.0% and 1.3% stearic acid in the greenhouse and field respectively. A ten-seed analysis of this line showed the following fatty acid composition: C_{16:0} - 4.0%, C_{18:0} - 1.0%, C_{18:1} - 66.5%, C_{18:2} - 18:4%, C_{18:3} - 7.2%, saturates - 30 5.0%, Total Saturates - 6.1%. In a single location replicated yield trial M3054.7 was not significantly different in yield from the parent cultivar Westar. M3054.7 was crossed to M3052.1 for allelism studies.

- 40 -

Fatty acid composition of the F_2 seed showed the two lines to be allelic. The mutational events in M3054.7, M3051.10 and M3052.1 although different in origin were in the same gene.

5 <u>EXAMPLE_6</u>

parent cultivar Westar.

High Oleic Acid Canola Lines

In the studies of Example 1, at the M3 generation, 31 lines exceeded the upper statistical threshold for oleic acid (\geq 71.0%). Line W7608.3 had 71.2% oleic acid. 10 At the M₄ generation, its selfed progeny (W7608.3.5, since designated A129.5) continued to exceed the upper statistical threshold for C_{18:1} with 78.8% oleic acid. seed of five self-pollinated plants of line A129.5 (ATCC 40811) averaged 75.0% oleic acid. A single plant 15 selection, Al29.5.3 had 75.6% oleic acid. The fatty acid composition of this high oleic acid mutant, which was stable under both field and greenhouse conditions to the M, generation, is summarized in Table IX. This line also stably maintained its mutant fatty acid composition to 20 the M, generation in field trials in multiple locations. Over all locations the self-pollinated plants (A129) averaged 78.3% oleic acid. The fatty acid composition of the A129 for each Idaho trial location are summarized in Table X. In multiple location replicated yield trials, 25 Al29 was not significantly different in yield from the

The canola oil of A129, after commercial processing, was found to have superior oxidative stability compared to Westar when measured by the Accelerated Oxygen Method (AOM), American Oil Chemists' Society Official Method Cd 12-57 for fat stability; Active Oxygen Method (revised 1989). The AOM of Westar was 18 AOM hours and for A129 was 30 AOM hours.

Sats=Total Saturate Content

The genetic relationship of the high oleic acid 25 mutation A129 to other oleic desaturases was demonstrated in crosses made to commercial canola cultivars and a low linolenic acid mutation. Al29 was crossed to the commercial cultivar Global ($C_{16:0}$ - 4.5%, $C_{18:0}$ - 1.5%, $C_{18:1}$ - 62.9%, $C_{18:2}$ - 20.0%, $C_{18:3}$ - 7.3%). Approximately 200 F_2 30 individuals were analyzed for fatty acid composition. The results are summarized in Table XB. The segregation fit 1:2:1 ratio suggesting a single co-dominant gene

- 42 -

controlled the inheritance of the high oleic acid phenotype.

5

- 43 -

An additional high oleic acid line, designated A128.3, was also produced by the disclosed method. A 50-seed bulk analysis of this line showed the following fatty acid composition: C_{16:0} - 3.5%, C_{18:0} - 1.8%, C_{18:1} - 77.3%, C_{18:2} - 9.0%, C_{18:3} - 5.6%, FDA Sats - 5.3%, Total Sats - 6.4%. This line also stably maintained its mutant fatty acid composition to the M₇ generation. In multiple locations replicated yield trials, A128 was not significantly different in yield from the parent cultivar Westar.

A129 was crossed to A128.3 for allelism studies. Fatty acid composition of the F_2 seed showed the two lines to be allelic. The mutational events in A129 and A128.3 although different in origin were in the same gene.

An additional high oleic acid line, designated M3028.-10 (ATCC 75026), was also produced by the disclosed method in Example 1. A 10-seed bulk analysis of this line showed the following fatty acid composition: C_{16:0} - 3.5%, C_{18:0} - 1.8%, C_{18:1} - 77.3%, C_{18:2} - 9.0%, C_{18:3} - 20 5.6%, FDA Saturates - 5.3%, Total Saturates - 6.4%. In a single location replicated yield trial M3028.10 was not significantly different in yield from the parent cultivar Westar.

EXAMPLE 7

Low Linoleic Acid Canola

25

In the studies of Example 1, at the M₃ generation, 80 lines exceeded the lower statistical threshold for linoleic acid (≤ 13.2%). Line W12638.8 had 9.4% linoleic acid. At the M₄ and M₅ generations, its selfed progenies [W12638.8, since designated A133.1 (ATCC 40812)] continued to exceed the statistical threshold for low C₁8:2 with linoleic acid levels of 10.2% and 8.4%, respectively. The fatty acid composition of this low linoleic acid mutant, which was stable to the M₃ generation under both field and greenhouse conditions, is

- 44 -

summarized in Table XI. In multiple location replicated yield trials, A133 was not significantly different in yield from the parent cultivar Westar. An additional low linoleic acid line, designated M3062.8 (ATCC 75025), was also produced by the disclosed method. A 10-seed bulk analysis of this line showed the following fatty acid composition: C_{16:0} - 3.8%, C_{18:0} - 2.3%, C_{18:1} - 77.1%, C_{18:2} - 8.9%, C_{18:3} - 4.3%, FDA Sats-6.1%. This line has also stably maintained its mutant fatty acid composition in the field and greenhouse.

TABLE XI

EXAMPLE 8

Low Linolenic and Linoleic Acid Canola

In the studies of Example 1, at the M_3 generation, 30 57 lines exceeded the lower statistical threshold for linolenic acid ($\leq 5.3\%$). Line W14749.8 had 5.3% linolenic acid and 15.0% linoleic acid. At the M_4 and M_5

bSats=Total Saturate Content

- 45 -

generations, its selfed progenies [W14749.8, since designated M3032 (ATCC 75021)] continued to exceed the statistical threshold for low $C_{18:3}$ with linolenic acid levels of 2.7% and 2.3%, respectively, and for a low sum of linolenic and linoleic acids with totals of 11.8% and 12.5% respectively. The fatty acid composition of this low linolenic acid plus linoleic acid mutant, which was stable to the $M_{\rm S}$ generation under both field and greenhouse conditions, is summarized in Table XII. In a single location replicated yield trial M3032 was not significantly different in yield from the parent cultivar (Westar).

EXAMPLE 9

The high oleic acid mutation of A129 was introduced into different genetic backgrounds by crossing and selecting for fatty acid and agronomic

30 characteristics. A129 (now renamed IMC 129) was crossed to Legend, a commercial spring Brassica napus variety. Legend has the following fatty acid composition: C_{16.0} - 3.8%, C_{18:0} - 2.1%, C_{18:1} - 63.1%, C_{18:2} - 17.8%, C_{18:3} - 9.3%.

- 46 -

The cross and progeny resulting from were coded as 89B60303.

The F₁ seed resulting from the cross was planted in the greenhouse and self-pollinated to produce F₂ seed.

The F₂ seed was planted in the field for evaluation.

Individual plants were selected in the field for agronomic characteristics. At maturity, the F₃ seed was harvested from each selected plant and analyzed for fatty acid composition.

Individuals which had fatty acid profiles similar to the high oleic acid parent (IMC 129) were advanced back to the field. Seeds (F₃) of selected individuals were planted in the field as selfing rows and in plots for preliminary yield and agronomic evaluations. At flowering the F₃ plants in the selfing rows were selfpollinated. At maturity the F₄ seed was harvested from individual plants to determine fatty acid composition. Yield of the individual selections was determined from the harvested plots.

Based on fatty acid composition of the individual plants and yield and agronomic characteristics of the plots F₄ lines were selected and advanced to the next generation in the greenhouse. Five plants from each selected line were self-pollinated. At maturity the F₅ seed was harvested from each and analyzed for fatty acid composition.

The F_5 line with the highest oleic fatty profile was advanced to the field as a selfing row. The remaining F_5 seed from the five plants was bulked together 30 for planting the yield plots in the field. At flowering, the F_5 plants in each selfing-row were self-pollinated. At maturity the F_6 self-pollinated seed was harvest from the selfing row to determine fatty acid composition and select for the high oleic acid trait. Yield of the

- 47 -

individual selections was determined from the harvested plots.

Fifteen F₆ lines having the high oleic fatty profile of IMC 129 and the desired agronomic 5 characteristics were advanced to the greenhouse to increase seed for field trialing. At flowering the F6 plants were self-pollinated. At maturity the F, seed was harvested and analyzed for fatty acid composition. F, seed lines which had fatty acid profiles most similar 10 to IMC 129 (Table XIII) were selected and planted in the field as selfing rows, the remaining seed was bulked together for yield trialing. The high oleic fatty acid profile of IMC 129 was maintained through seven generations of selection for fatty acid and agronomic 15 traits in an agronomic background of Brassica napus which was different from the parental lines. Thus, the genetic trait from IMC 129 for high oleic acid can be used in the development of new high oleic Brassica napus varieties.

TABLE XIII

20 Fatty Acid Composition of Advanced Breeding Generation
with High Oleic Acid Trait (IMC 129 X Legend)

		Fatty Acid Composition(%)					
25	F, Selections of 89B60303	C _{16:0}	C _{18:0}	C _{18:1}	C _{18:2}	C _{18:3}	
	93.06194 93.06196 93.06198	3.8 4.0 3.7	1.6 2.8 2.2	78.3 77.3 78.0	7.7 6.8 7.4	4.4 3.4 4.2	

The high oleic acid trait of IMC 129 was also introduced into a different genetic background by combining crossing and selection methods with the generation of dihaploid populations from the microspores of the F₁ hybrids. IMC 129 was crossed to Hyola 41, a commercial spring Brassica napus variety. Hyola 41 has the following fatty acid composition: C_{16:0} - 3.8%, C_{18:0} -

- 48 -

2.7%, $C_{18:1}$ - 64.9%, $C_{18:2}$ - 16.2%, $C_{18:3}$ - 9.1%. The cross and progeny resulting from the cross were labeled 90DU.146.

The F₁ seed was planted from the cross and a 5 dihaploid (DH₁) population was made from the F₁ microspores using standard procedures for Brassica napus. Each DH, plant was self-pollinated at flowering to produce DH₁ seed. At maturity the DH₁ seed was harvested and analyzed for fatty acid composition. DH, individuals 10 which expressed the high oleic fatty acid profit of IMC 129 were advanced to the next generation in the greenhouse. For each individual selected five DH, seeds were planted. At flowering the DH2 plants were selfpollinated. At maturity the DH₂ seed was harvested and 15 analyzed for fatty acid composition. The DH2 seed which was similar in fatty acid composition to the IMC 129 parent was advanced to the field as a selfing row. remaining DH, seed of that group was bulked and planted in plots to determine yield and agronomic characteristics of 20 the line. At flowering individual DH, plants in the selfing row were self-pollinated. At maturity the DH₃ seed was harvested from the individual plants to determine fatty acid composition. Yield of the selections was determined from the harvested plots. 25 Based on fatty acid composition, yield and agronomic characteristics selections were advanced to the next generation in the greenhouse. The DH, seed produced in the greenhouse by self-pollination was analyzed for fatty acid composition. Individuals which were similar to the 30 fatty acid composition of the IMC 129 parent were advanced to the field to test for fatty acid stability and yield evaluation. The harvested DH, seed from six locations maintained the fatty acid profile of the IMC 129 parent (Table XIV).

EXAMPLE 10 Canola Lines 0508 and 04275

15

Seeds of the B. napus line IMC-129 were mutagenized with methyl N-nitrosoguanidine (MNNG). The MNNG treatment consisted of three parts: pre-soak,

20 mutagen application, and wash. A 0.05M Sorenson's phosphate buffer was used to maintain pre-soak and mutagen treatment pH at 6.1. Two hundred seeds were treated at one time on filter paper (Whatman #3M) in a petri dish (100mm x 15mm). The seeds were pre-soaked in 15 mls of 0.05M Sorenson's buffer, pH 6.1, under continued agitation for two hours. At the end of the pre-soak period, the buffer was removed from the plate.

A 10mM concentration of MNNG in 0.05M Sorenson's buffer, pH 6.1, was prepared prior to use. Fifteen ml of 10m MNNG was added to the seeds in each plate. The seeds were incubated at 22°C±3°C in the dark under constant agitation for four (4) hours. At the end of the incubation period, the mutagen solution was removed.

The seeds were washed with three changes of distilled water at 10 minute intervals. The fourth wash

- 50 -

was for thirty minutes. This treatment regime produced an LD60 population.

Treated seeds were planted in standard greenhouse potting soil and placed into an environmentally

5 controlled greenhouse. The plants were grown under sixteen hours of light. At flowering, the racemes were bagged to produce selfed seed. At maturity, the M2 seed was harvested. Each M2 line was given an identifying number. The entire MNNG-treated seed population was designated as the Q series.

Harvested M2 seeds was planted in the greenhouse. The growth conditions were maintained as previously described. The racemes were bagged at flowering for selfing. At maturity, the selfed M3 seed was harvested and analyzed for fatty acid composition. For each M3 seed line, approximately 10-15 seeds were analyzed in bulk as described in Example 1.

High oleic-low linoleic M3 lines were selected from the M3 population using a cutoff of >82% oleic acid and <5.0% linoleic. From the first 1600 M3 lines screened for fatty acid composition, Q508 was identified. The Q508 M3 generation was advanced to the M4 generation in the greenhouse. Table XV shows the fatty acid composition of Q508 and IMC 129. The M4 selfed seed maintained the selected high oleic-low linoleic acid phenotype (Table XVI).

TABLE XV

Fatty Acid Composition of A129 and High
Oleic Acid M3 Mutant O508

30	Line #	16:0	18:0	18:1	18:2	18:3
	A129*	4.0	2.4	77.7	7.8	4.2
	Q508	3.9	2.1	84.9	2.4	2.9

^{*}Fatty acid composition of Al29 is the average of 50 self-pollinated plants grown with the M3 population

- 51 -

M₄ generation Q508 plants had poor agronomic qualities in the field compared to Westar. Typical plants were slow growing relative to Westar, lacked early vegetative vigor, were short in stature, tended to be chlorotic and had short pods. The yield of Q508 was very low compared to Westar.

The M_4 generation Q508 plants in the greenhouse tended to be reduced in vigor compared to Westar. However, Q508 yields in the greenhouse were greater than Q508 yields in the field.

TABLE XVI

Fatty Acid Composition of Seed Oil

from Greenhouse-Grown Q508, IMC 129 and Westar.

	Line	16:0	18:0	18:1	18:2	18:3	FDA Sats
15	IMC 129ª	4.0	2.4	77.7	7.8	4.2	6.4

; ;	Q508°	3.9	2.1	84.9	2.4	2.9	6.0

aAverage of 50 self-pollinated plants

Nine other M4 high-oleic low-linoleic lines were also identified: Q3603, Q3733, Q4249, Q6284, Q6601, Q6761, Q7415, Q4275, and Q6676. Some of these lines had good agronomic characteristics and an elevated oleic acid level in seeds of about 80% to about 84%.

Q4275 was crossed to the variety Cyclone. After selfing for seven generations, mature seed was harvested from 93GS34-179, a progeny line of the Q4275 Cyclone cross. Referring to Table XVII, fatty acid composition of a bulk seed sample shows that 93GS34 retained the seed fatty acid composition of Q4275. 93GS34-179 also maintained agronomically desirable characteristics.

²⁰ bData from Example 1

^cAverage of 50 self-pollinated plants

- 52 -

After more than seven generations of selfing of Q4275, plants of Q4275, IMC 129 and 93GS34 were field grown during the summer season. The selections were tested in 4 replicated plots (5 feet X 20 feet) in a 5 randomized block design. Plants were open pollinated. No selfed seed was produced. Each plot was harvested at maturity, and a sample of the bulk harvested seed from each line was analyzed for fatty acid composition as described above. The fatty acid compositions of the 10 selected lines are shown in Table XVII.

Table XVII

Fatty Acid Composition of

Field Grown IMC 129, Q4275 and 93GS34 Seeds

	Line		Fatty	Acid	Compos	ition (%)
		C _{16:0}	C _{18:0}	C _{18:1}	C _{18:2}	C _{18:3}	FDA Sats
15	IMC 129	3.3	2.4	76.7	8.7	5.2	5.7
	Q4275	3.7	3.1	82.1	4.0	3.5	6.8
	93GS34-179	2.6	2.7	85.0	2.8	3.3	5.3

The results shown in Table XVII show that Q4275 maintained the selected high oleic - low linoleic acid phenotype under field conditions. The agronomic characteristics of Q4275 plants were superior to those of Q508.

M₄ generation Q508 plants were crossed to a dihaploid selection of Westar, with Westar serving as the female parent. The resulting F1 seed was termed the 92EF population. About 126 F1 individuals that appeared to have better agronomic characteristics than the Q508 parent were selected for selfing. A portion of the F₂ seed from such individuals was replanted in the field.

30 Each F2 plant was selfed and a portion of the resulting F3 seed was analyzed for fatty acid composition. The content of oleic acid in F₃ seed ranged from 59 to 79%.

- 53 -

No high oleic (>80%) individuals were recovered with good agronomic type.

A portion of the F₂ seed of the 92EF population was planted in the greenhouse to analyze the genetics of the Q508 line. F₃ seed was analyzed from 380 F2 individuals. The C_{18:1} levels of F₃ seed from the greenhouse experiment is depicted in Figure 1. The data were tested against the hypothesis that Q508 contains two mutant genes that are semi-dominant and additive: the original IMC 129 mutation as well as one additional mutation. The hypothesis also assumes that homozygous Q508 has greater than 85% oleic acid and homozygous Westar has 62-67% oleic acid. The possible genotypes at each gene in a cross of Q508 by Westar may be designated as:

AA = Westar Fad2^a
BB = Westar Fad2^b
aa = Q508 Fad2^a
bb = Q508 Fad2^b

Assuming independent segregation, a 1:4:6:4:1 ratio of phenotypes is expected. The phenotypes of heterozygous plants are assumed to be indistinguishable and, thus, the data were tested for fit to a 1:14:1 ratio of homozygous Westar: heterozygous plants: homozygous Q508.

25	Phenotypic	# of	
	<u>Ratio</u>	Westar Alleles	Genotype
	1	4	AABB(Westar)
	4	3	AABb, AaBB, AABb, AaBB
	6	2	AaBb, AAbb, AaBb, AaBb, aaBB, AaBb
30	4	1	Aabb, aaBb, Aabb, aaBb
	1	0	aabb (Q508)

Using Chi-square analysis, the oleic acid data fit a 1:14:1 ratio. It was concluded that Q508 differs from

- 54 -

Westar by two major genes that are semi-dominant and additive and that segregate independently. By comparison, the genotype of IMC 129 is aaBB.

The fatty acid composition of representative F3 individuals having greater than 85% oleic acid in seed oil is shown in Table XVIII. The levels of saturated fatty acids are seen to be decreased in such plants, compared to Westar.

EXAMPLE 11

Leaf and Root Fatty Acid Profiles of Canola Lines IMC-129, 0508, and Westar

Plants of Q508, IMC 129 and Westar were grown in the greenhouse. Mature leaves, primary expanding leaves, petioles and roots were harvested at the 6-8 leaf stage, frozen in liquid nitrogen and stored at -70°C. Lipid extracts were analyzed by GLC as described in Example 1. The fatty acid profile data are shown in Table XIX.

The data in Table XIX indicate that total leaf lipids in Q508 are higher in $C_{18:1}$ content than the $C_{18:2}$ plus $C_{18:3}$ content. The reverse is true for Westar and IMC 129. The difference in total leaf lipids between Q508 and IMC 129 is consistent with the hypothesis that a second Fad2 gene is mutated in Q508.

The C_{16:3} content in the total lipid fraction was about the same for all three lines, suggesting that the plastid FadC gene product was not affected by the Q508 mutations. To confirm that the FadC gene was not 20 mutated, chloroplast lipids were separated and analyzed. No changes in chloroplast C_{16:1}, C_{16:2} or C_{16:3} fatty acids were detected in the three lines. The similarity in plastid leaf lipids among Q508, Westar and IMC 129 is consistent with the hypothesis that the second mutation in Q508 affects a microsomal Fad2 gene and not a plastid FadC gene.

10 EXAMPLE 12

5

Sequences of Mutant and Wild-Type Delta-12 Fatty Acid Desaturases from B. napus

Primers specific for the FAD2 structural gene were used to clone the entire open reading frame (ORF) of the D and F 12-DES genes by reverse transcriptase polymerase chain reaction (RT-PCR). RNA from seeds of IMC 129, Q508 and Westar plants was isolated by standard methods and was used as template. The RT-amplified fragments were used for nucleotide sequence determination. The DNA sequence of each gene from each line was determined from both strands by standard dideoxy sequencing methods.

Sequence analysis revealed a G to A transversion at nucleotide 316 (from the translation initiation codon) of the D gene in both IMC 129 (SEQ ID NO:3) and Q508, compared to the sequence of Westar (SEQ ID NO:1). The transversion changes the codon at this position from GAG to AAG and results in a non-conservative substitution of glutamic acid, an acidic residue, for lysine a basic residue. The presence of the same mutation in both lines was expected since the Q508 line was derived from IMC 129. The same base change was also detected in Q508

- 57 -

and IMC 129 when RNA from leaf tissue was used as template.

The G to A mutation at nucleotide 316 was confirmed by sequencing several independent clones

5 containing fragments amplified directly from genomic DNA of IMC 129 and Westar. These results eliminated the possibility of a rare mutation introduced during reverse transcription and PCR in the RT-PCR protocol. It was concluded that the IMC 129 mutant is due to a single base transversion at nucleotide 316 in the coding region of the D gene of rapeseed microsomal delta 12-desaturase.

A single base transition from T to A at nucleotide 515 of the F gene was detected in Q508 compared to the Westar sequence. The mutation changes the codon at this position from CTC to CAC, resulting in the non-conservative substitution of a non-polar residue, leucine, for a polar residue, histidine, in the resulting gene product. No mutations were found in the F gene sequence of IMC 129 compared to the F gene sequence of Westar.

These data support the conclusion that a mutation in a delta-12 desaturase gene sequence results in alterations in the fatty acid profile of plants containing such a mutated gene. Moreover, the data show that when a plant line or species contains two delta-12 desaturase loci, the fatty acid profile of an individual having two mutated loci differs from the fatty acid profile of an individual having one mutated locus.

The mutation in the D gene of IMC 129 and Q508
30 mapped to a region having a conserved amino acid motif
(His-Xaa-Xaa-Xaa-His) found in cloned delta-12 and delta15 membrane bound-desaturases (Table XX).

EXAMPLE 13

Transcription and Translation of Microsomal Delta-12
Fatty Acid Desaturases

analysis of stage II and stage III developing seeds and leaf tissue. The primers used to specifically amplify 12-DES F gene RNA from the indicated tissues were sense primer 5'-GGATATGATGATGGTGAAAGA-3' and antisense primer 5'-TCTTTCACCATCATCATATCC-3'. The primers used to specifically amplify 12-DES D gene RNA from the indicated tissues were sense primer 5'-GTTATGAAGCAAAGAAAC-3' and antisense primer 5'-GTTTCTTTGCTTCATAAC-3'. The results indicated that mRNA of both the D and F gene was expressed in seed and leaf tissues of IMC 129, Q508 and wild type Westar plants.

- 59 -

In vitro transcription and translation analysis showed that a peptide of about 46 kD was made. This is the expected size of both the D gene product and the F gene product, based on sum of the deduced amino acid sequence of each gene and the cotranslational addition of a microsomal membrane peptide.

These results rule out the possibility that nonsense or frameshift mutations, resulting in a truncated
polypeptide gene product, are present in either the
mutant D gene or the mutant F gene. The data, in
conjunction with the data of Example 12, support the
conclusion that the mutations in Q508 and IMC 129 are in
delta-12 fatty acid desaturase structural genes encoding
desaturase enzymes, rather than in regulatory genes.

15 EXAMPLE 14

Development of Gene-Specific PCR Markers

Based on the single base change in the mutant D gene of IMC 129 described in above, two 5' PCR primers were designed. The nucleotide sequence of the primers 20 differed only in the base (G for Westar and A for IMC 129) at the 3' end. The primers allow one to distinguish between mutant fad2-D and wild-type Fad2-D alleles in a DNA-based PCR assay. Since there is only a single base difference in the 5' PCR primers, the PCR assay is very 25 sensitive to the PCR conditions such as annealing temperature, cycle number, amount, and purity of DNA templates used. Assay conditions have been established that distinguish between the mutant gene and the wild type gene using genomic DNA from IMC 129 and wild type 30 plants as templates. Conditions may be further optimized by varying PCR parameters, particularly with variable crude DNA samples. A PCR assay distinguishing the single base mutation in IMC 129 from the wild type gene along with fatty acid composition analysis provides a means to

- 60 **-**

simplify segregation and selection analysis of genetic crosses involving plants having a delta-12 fatty acid desaturase mutation.

EXAMPLE 15

Transformation with Mutant and Wild Type Fad3 Genes

5

B. napus cultivar Westar was transformed with mutant and wild type Fad3 genes to demonstrate that the mutant Fad3 gene for canola cytoplasmic linoleic desaturase 15-DES is nonfunctional. Transformation and regeneration were performed using disarmed Agrobacterium tumefaciens essentially following the procedure described in WO 94/11516.

Two disarmed Agrobacterium strains were engineered, each containing a Ti plasmid having the appropriate gene linked to a seed-specific promoter and a corresponding termination sequence. The first plasmid, pIMC110, was prepared by inserting into a disarmed Ti vector the full length wild type Fad3 gene in sense orientation (nucleotides 208 to 1336 of SEQ ID 6 in WO 93/11245), flanked by a napin promoter sequence positioned 5' to the Fad3 gene and a napin termination sequence positioned 3' to the Fad3 gene. The rapeseed napin promoter is described in EP 0255378.

The second plasmid, pIMC205, was prepared by

25 inserting a mutated Fad3 gene in sense orientation into a
disarmed Ti vector. The mutant sequence contained
mutations at nucleotides 411 and 413 of the microsomal
Fad3 gene described in W093/11245, thus changing the
sequence for codon 96 from GAC to AAG. The amino acid at

30 codon 96 of the gene product was thereby changed from
aspartic acid to lysine. See Table XX. A bean
(Phaseolus vulgaris) phaseolin (7S seed storage protein)
promoter fragment of 495 base pairs, starting with 5'TGGTCTTTTGGT-3', was placed 5' to the mutant Fad3 gene

35 and a phaseolin termination sequence was placed 3' to the

PCT/US96/20090 WO 97/21340

- 61 -

mutant Fad3 gene. The phaseolin sequence is described in Doyle et al., (1986) J. Biol. Chem. 261:9228-9238) and Slightom et al., (1983) Proc. Natl. Acad. Sci. USA 80:1897-1901.

The appropriate plasmids were engineered and transferred separately to Agrobacterium strain LBA4404. Each engineered strain was used to infect 5 mm segments of hypocotyl explants from Westar seeds by cocultivation. Infected hypocotyls were transferred to callus medium 10 and, subsequently, to regeneration medium. Once discernable stems formed from the callus, shoots were excised and transferred to elongation medium. The elongated shoots were cut, dipped in Rootone™, rooted on an agar medium and transplanted to potting soil to obtain 15 fertile T1 plants. T2 seeds were obtained by selfing the resulting T1 plants.

Fatty acid analysis of T2 seeds was carried out as described above. The results are summarized in Table Of the 40 transformants obtained using the pIMC110 20 plasmid, 17 plants demonstrated wild type fatty acid profiles and 16 demonstrated overexpression. A proportion of the transformants are expected to display an overexpression phenotype when a functioning gene is transformed in sense orientation into plants.

Of the 307 transformed plants having the pIMC205 gene, none exhibited a fatty acid composition indicative of overexpression. This result indicates that the mutant fad3 gene product is non-functional, since some of the transformants would have exhibited an overexpression 30 phenotype if the gene product were functional.

30

Fatty acid compositions of representative transformed plants are presented in Table XXII. Lines 652-09 and 663-40 are representative of plants containing pIMC110 and exhibiting an overexpression and a cosuppression phenotype, respectively. Line 205-284 is representative of plants containing pIMC205 and having the mutant fad3 gene.

Table XXII

Fatty Acid Composition of T2 Seed From Westar Transformed With pIMC205 or pIMC110.

Line	Patty Acid Composition (%)									
	C16:0	C18:0	C18:1	C18:2	C18:3					
652-09 pIMC110 overexpression	4.7	3.3	65.6	8.1	14.8					
663-40 pIMC110 co-suppression	4.9	2.1	62 . 5	23.2	3.6					
205-284 pIMC205	3.7	1.8	68.8	15.9	6.7					

To the extent not already indicated, it will be understood by those of ordinary skill in the art that any one of the various specific embodiments herein described and illustrated may be further modified to incorporate features shown in other of the specific embodiments.

The foregoing detailed description has been provided for a better understanding of the invention only and no unnecessary limitation should be understood therefrom as some modifications will be apparent to those

- 63 -

skilled in the art without deviating from the spirit and scope of the appended claims.

WHAT IS CLAIMED IS:

- 1. An isolated nucleic acid fragment comprising a sequence of at least about 10 nucleotides from a Brassicaceae or Helianthus delta-12 fatty acid desaturase gene having at least one mutation, wherein said gene is effective for altering fatty acid composition in Brassicaceae or Helianthus seeds and wherein said sequence includes said at least one mutation.
- 2. The nucleic acid fragment of claim 1, wherein said sequence comprises a full-length coding sequence of said gene.
 - The nucleic acid fragment of claim 1, wherein said mutant desaturase gene encodes a microsomal gene product.
- 4. The nucleic acid fragment of claim 1, wherein said at least one mutation comprises a mutation in a region of said desaturase gene encoding a His-Glu-Cys-Gly-His amino acid motif.
- 5. The nucleic acid fragment of claim 4, wherein said at least one mutation comprises a non-conservative amino acid substitution in said region.
 - The nucleic acid fragment of claim 5, wherein said at least one mutation comprises the sequence His-Lys-Cys-Gly-His.
- 7. The nucleic acid fragment of claim 1, wherein said 25 mutant desaturase gene is from a Brassica napus plant.
 - 8. The nucleic acid fragment of claim 1, wherein said gene is the D form of a Brassicaceae microsomal gene.

- 78 -

- 9. The nucleic acid fragment of claim 1, wherein said at least at least one mutation comprises the sequence Lys-Tyr-His-Asn-Asn-Pro.
- 10. A plant of the Brassicaceae or Helianthus families other than Brassica napus, said plant containing a sequence of at least 10 nucleotides from a delta-12 fatty acid desaturase gene having at least one mutation, said at least one mutation in a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif and wherein said mutation confers an altered fatty acid composition in seeds of said plant.
 - 11. The plant of claim 10, wherein said plant contains a full-length coding sequence of said mutant gene.
- 12. The plant of claim 10, wherein said motif 15 comprises the sequence His-Glu-Cys-Gly-His.
 - 13. The plant of claim 10, wherein said gene is from a Brassica napus plant.
 - 14. The plant of claim 10, wherein said plant is a Brassica rapa plant.
- 20 15. An isolated nucleic acid fragment comprising a sequence of at least about 10 nucleotides from a Brassicaceae or Helianthus delta-15 fatty acid desaturase gene having at least one mutation, wherein said gene is effective for altering fatty acid composition in
- 25 Brassicaceae or Helianthus seeds and wherein said sequence includes said at least one mutation.

- 79 -

- 16. The nucleic acid fragment of claim 15, wherein said sequence comprises a full-length coding sequence of said gene.
- 17. The nucleic acid fragment of claim 15, wherein said at least one mutation comprises a mutation in a region of said desaturase gene encoding a His-Asp-Cys-Gly-His amino acid motif.
- 18. The nucleic acid fragment of claim 15, wherein said mutant desaturase gene is from a Brassica napus
 10 plant.
- 19. A Brassicaceae or Helianthus plant containing a sequence of at least 10 nucleotides from a delta-15 fatty acid desaturase gene having at least one mutation, said at least one mutation in a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif and wherein said mutation confers an altered fatty acid composition in seeds of said plant.
 - The plant of claim 19, wherein said plant contains a full-length coding sequence of said mutant gene.
- 20 21. The plant of claim 19, wherein said motif comprises the sequence His-Asp-Cys-Gly-His.
 - The plant of claim 19, wherein said mutant desaturase gene is from a Brassica napus plant.
- 23. The plant of claim 19, wherein said plant is a 25 Brassica napus plant.
 - 24. A Brassicaceae or Helianthus plant containing:

5

10

- 80 -

- a) a sequence of at least about 10 nucleotides from a delta-12 fatty acid desaturase gene having at least one mutation, said at least one delta-12 gene mutation in a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif;
- b) a sequence of at least 10 nucleotides from a delta-15 fatty acid desaturase gene having at least one mutation, said at least one delta-15 gene mutation in a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif, said delta-12 gene mutation and said delta-15 gene mutation conferring an altered fatty acid composition in seeds of said plant.
- 25. A Brassicaceae or Helianthus plant containing a

 15 sequence of at least about 10 nucleotides from a delta-12 fatty acid desaturase gene having at least one mutation, said at least one mutation in a region encoding a TyrLeu-Asn-Asn-Pro amino acid motif and wherein said mutation confers an altered fatty acid composition in

 20 seeds of said plant.
 - 26. A vegetable oil extracted from seeds produced by the plant of claim 10.
- 27. The oil of claim 26, wherein said oil has, following crushing and extraction of said seeds, from about 1% to about 10% linoleic acid based on total fatty acid composition.
 - The oil of claim 26, wherein said oil has from about 69% to about 90% oleic acid based on total fatty acid composition.

- 81 -

- 29. A vegetable oil extracted from seeds produced by the plant of claim 19.
- 30. The oil of claim 29, wherein said oil has, following crushing and extraction of said seeds, from about 0.5% to about 10% α-linolenic acid based on total fatty acid composition.
 - 31. A vegetable oil extracted from seeds produced by the plant of claim 24.
- 32. A vegetable oil extracted from seeds produced by 10 the plant of claim 25.
 - 33. A method for producing a Brassicaceae or Helianthus plant line, comprising the steps of:

20

25

- a) inducing mutagenesis in cells of a starting variety of a Brassicaceae or Helianthus species;
- b) obtaining one or more progeny plants from said cells;
 - c) identifying at least one of said progeny plant that contains a delta-12 fatty acid desaturase gene having at least one mutation, said at least one mutation in a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif; and
 - d) producing said plant line from said at least one progeny plant by self- or cross-pollination, said plant line having said at least one delta-12 gene mutation.
 - The method of claim 33, wherein said plant line produces seeds yielding an oil having a stabilized linoleic acid content from about 1% to about 14%.

- 82 -

35. The method of claim 33, further comprising the steps of:

- e) inducing mutagenesis in cells of said plant line;
- f) obtaining one or more progeny plants from said plant line cells;

10

15

- g) identifying at least one of said plant line progeny plants that contains a delta-15 fatty acid desaturase gene having at least one delta-15 gene mutation, said at least one delta-15 gene mutation in a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif;
- h) producing a second plant line from said at least one plant line progeny plant by self- or cross-pollination, said second plant line having said at least one delta-12 gene mutation and said at least one delta-15 gene mutation.
- The method of claim 33, wherein said starting variety is a *Brassica napus* variety.
- 20 37. The method of claim 36, wherein said mutation is in a first form of delta-12 fatty acid desaturase.
- 38. The method of claim 37, further comprising the step of crossing a plant of said plant line to a plant having a mutation in a second form of delta-12 fatty acid desaturase.
 - 39. The method of claim 38, wherein said second mutation is in a region other than a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif.
- 40. The method of claim 36, further comprising the 30 steps of:

- 83 -

- e) inducing mutagenesis in cells of said plant line;
- f) obtaining one or more progeny plants from said plant line cells;
- g) identifying at least one of said plant line progeny plants that contains a second delta-12 fatty acid desaturase gene having at least one mutation, said second gene mutation in a region other than a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif; and
- h) producing a second plant line from said at least one plant line progeny plant by self- or cross-pollination, said second plant line having said first delta-12 gene mutation and said second delta-12 gene mutation.
- 41. A method for producing a Brassicaceae or Helianthus plant line, comprising the steps of:

5

10

15

20

25

30

- a) inducing mutagenesis in cells of a starting variety of a Brassicaceae or Helianthus species;
- b) obtaining one or more progeny plants from said cells;
 - c) identifying at least one of said progeny plants that contains a delta-15 fatty acid desaturase gene having at least one mutation, said at least one mutation in a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif; and
 - d) producing said plant line from said at least one progeny plant by self- or cross-pollination, said plant line having said delta-15 gene mutation.
